Flat springs - Designing Buildings Wiki -  
Share your construction industry  
knowledge. Flat springs are flat strips of  
material which, when deflected by an  
external load, store and release energy.  
These types of spring are small, stamped  
metal components that function like a  
spring by controlling deflection within small  
or restricted spaces.

7.1.1 Spring Design Procedures 1.

Determine what spring rate and deflection or spring travel is required for your particular application. Also, determine the energy requirements. 2. Determine the space limitations in which the spring is required to work and try to design the spring accordingly, using a parallel arrangement if required, or allow space in the mechanism for the spring per its calculated design dimensions. 3.

Spring design is an interactive process, and may require repeating operations until the best design is achieved. Because of spring complexity, many simplifying assumptions are made in the design process. These assumptions have proven over the years to be reliable. But because such assumptions exist, the calculations are not always exact.

The Design Guide is separated into life cycle charts, which include commonly chosen life cycle amounts. Common life cycles range from 4,000 to about 25,000 life cycles. If a high life cycle is needed, considerations have to be made for increased tolerances of the spring ' s diameter and force due to the low-stress level and slight variances in material.

There are two types of leaf spring used for vehicles; the multi leaf and the parabolic leaf spring. The multi leaf spring design is based on the use of a flat trapezoid geometry, with cut leaves stacked one on top of the other. This leads to a multi leaf design with different lengths of each leaf. When a multi leaf spring deflects the leaves move relative each other.
